

# INVESTIGATOR'S ANNUAL REPORT

## National Park Service

All or some of the information provided may be available to the public

<b>Reporting Year:</b> 2005	<b>Park:</b> Glacier Bay NP & PRES
<b>Principal Investigator:</b> Dr Lisa Etherington	<b>Office Phone:</b> 415-669-7494  <b>Email:</b> letherington@usgs.gov
<b>Address:</b> P.O. Box 645 Inverness, CA 94937 US	<b>Office Fax:</b> n/a
<b>Additional investigators or key field assistants (first name, last name, office phone, office email):</b>  No co-investigators	
<b>Permit#:</b> GLBA-2004-SCI-0005	
<b>Park-assigned Study Id. #:</b> GLBA-00058	
<b>Project Title:</b> Glacier Bay Oceanographic Patterns	
<b>Permit Start Date:</b> Mar 01, 2004	<b>Permit Expiration Date</b> Dec 31, 2010
<b>Study Start Date:</b> Jan 01, 1993	<b>Study End Date</b> Dec 31, 2043
<b>Study Status:</b> Continuing	
<b>Activity Type:</b> Monitoring	
<b>Subject/Discipline:</b> Coastal / Marine Systems	
<b>Objectives:</b> <p>The oceanographic patterns within Glacier Bay drive a large portion of the spatial and temporal variability of the ecosystem. A program that monitors oceanographic patterns is essential for understanding the marine ecosystem and to differentiate between natural variation and anthropogenic disturbance. The objective of this project is to understand the spatial and temporal (seasonal and yearly) variation in a variety of oceanographic parameters, including salinity, temperature, stratification, light levels, turbidity (sediment load), and chlorophyll-a (productivity).</p>	
<b>Findings and Status:</b> <p>2005 represented the thirteenth year of field sampling for this monitoring program and consisted of six surveys of twenty three stations located throughout Glacier Bay. Sampling during 2005 was conducted during January, March, June, July, October, and December. These time periods were chosen to represent spring bloom conditions (March), high chlorophyll-a levels (June and July), high stratification and turbidity levels (July), high precipitation conditions (October) and winter conditions (January, December). In addition, these months were chosen to give consistency in the timing of sampling among years. At each of the twenty-three stations during each of the sampling times, a vertical CTD profile of salinity, temperature, chlorophyll-a concentration (proxy for phytoplankton abundance), light penetration, and turbidity was taken at one meter intervals from surface waters to bottom depths (or maximum of 300m).</p> <p>Past oceanographic surveys combined with 2005 sampling in Glacier Bay demonstrate that oceanographic characteristics of the surface waters are relatively similar from November to February, while the periods March through October represent the greatest change, both spatially and temporally (among months). The upper-fjord regions of the Bay, located the farthest from marine waters and closest to glaciers, are the areas of greatest change among months of the year for all measured physical oceanographic factors except water temperature. Noticeable differences in oceanographic properties have been detected between the East and West Arms of the Bay, potentially due to differences in weather patterns between these regions as well as differences in sources of freshwater input and sediment loads. Patterns of salinity and stratification appear to be largely driven by the seasonal cycle of freshwater discharge in southeast Alaska. High levels of freshwater discharge from upper Bay regions promote stratification from spring through fall, while strong tidal currents over shallow sills enhance mixing. Elevated levels of chlorophyll-a within the surface waters do not coincide with surface water stratification in May, but instead, an overall increase in chlorophyll-a occurs in March, most likely as a response to an increase in available light. Levels of chlorophyll-a increases from spring to summer and remains relatively high into the fall. Highest levels of chlorophyll-a within</p>	

Glacier Bay are generally found within the central Bay and the lower reaches of the East and West Arms. These regions are likely favorable for phytoplankton populations due to intermediate stratification levels, higher light penetration due to decreased sediment concentrations in the water column, and nutrient regeneration.

In addition to oceanographic sampling this year, we also held a workshop to conduct an external review of the current operations of the oceanographic monitoring program and to develop recommendations for future work. An overview of the discussions and recommendations resulting from this workshop are currently being compiled.
